CSC 251 Python Documentation Requirements

All Python source code files should include an opening comment with information about the coder, course, assignment description, issues, and help received. From Lecture 01:

```
"""
  Author:  Emma Brown
  Email:  ebbrown@ncsu.edu
  Class:  CSC 295-002 Fall 2024
  Program:  Example code to demonstrate documentation
  Purpose:  Computes the amount of a restaurant bill split x ways
    after tax and tip
  Bugs: None
  Acknowledgements: Alexis helped me fix print errors
"""
```

Use docstring style notation in all functions to describe the function, show a list that includes each parameter and its type and a description of the value it holds, and the type and description of the value(s) returned. Since Python function headers do not indicate the parameter type, this is helpful to best utilize the function. Likewise, it's helpful to know the return variable type to match it in the caller. If a function does not return a value, indicate "None". An example:

```
def calc_tip(bill, percent):
    """Calculates percent tip on bill.
      Parameters:
        bill (float): cost of the meal
        percent (float): how much to tip
      Returns:
        tip (float): the amount of money to add for
    """
    tip = bill * (percent / 100.0)
    return tip
```

If you type the `help` with the function name within your code or Jupyter notebook, the docstring information is conveniently retrieved for you:

```
help(calc_tip)
```

Outputs:

```
Help on function calc_tip in module __main__:

calc_tip(bill, percent)
    Calculates percent tip on bill.
    Parameters:
      bill (float): cost of the meal
      percent (float): how much to tip
    Returns:
      tip (float): the amount of money to add for
```
